

MXC/cold-stage and TES active-region x'-z' cross sections

Same coordinate scale. Geometry envelopes are dimensionally aligned to the retained .geo files; CSG holes and small supports are omitted. Dots are exact selected delayed-source positions, sized by day-15 event weight.

SG3B: TES directly below the cold-stage stack

SH3 OptV3: TES displaced into the side chimney

- selected delayed source: DR/MXC/cold plate
- ✕ selected delayed source: other
- ▨ MXC and upper cold plates
- ▨ BPE envelope
- ▨ active BGO envelope
- ▨ plastic-veto envelope
- ▲ selected delayed source: TES-near structure
- TES active layers

Interpretation: moving TES out of the cold-plate projection suppresses cold-stage coupling, but any material placed around the TES can itself activate; geometric non-overlap does not remove the finite 511-keV photon solid angle.
